VISION STATEMENT

GWFA – The centre of choice for gathering and dispersing of forage and livestock information, providing a strong link with producers and the research community

MISSION STATEMENT

To enhance awareness of the organization as an information exchange centre, illustrating forage and livestock production practices that are environmentally and economically sustainable for the agricultural community.

Approved May 2012

26th Annual West Country Ag Tour

Thursday, August 22, 2013
Dovercourt Hall
7:30 am till 4:30 pm

Sign up for an exciting day filled with good company and delicious food! Enjoy the sights as we tour Clearwater County and visit a variety of agricultural operations to learn about research and innovations taking place in our area!

Pancake Breakfast
starts at 7:30 am!

Tour buses
depart right after
breakfast!

Coffee and snacks
will be provided!

Registration Fee: \$25 per person before August 15th
\$30 per person after August 15th

Includes breakfast, lunch, snacks, bus charge and an information package!

To register, please contact: Clearwater County Agricultural Services and Landcare
(403) 845-4444

Additional
Information

The tour will also feature a tradeshow during breakfast & lunch and a silent auction!

Hosted by:

Manager's Notes:

By Albert Kuipers

Recently we had the opportunity to visit Jim and Barb Bauer's Anchor JB Ranch as a bonus for participants of the Controlled Grazing School we held in June. Those who took advantage of this opportunity got a quick and dirty look at some of the concepts Jim teaches.

One of the main things Jim teaches in the grazing schools and conducts at the ranch is that of training the eye to be able to estimate the size of area needed to provide sufficient forage for a given amount of time, whether that be a half day, a day, or longer. This estimation is based on the density and quality of the forages available in the pasture, and the number and size of the livestock that will be grazing there.

Jim starts with having participants go into different pastures on the ranch to take yield clips, dry them, weigh them, and then calculate how much forage is available. From there he has participants go out in small groups and visually assess how much forage is in each inch of forage on a pounds per acre basis. Then, by multiplying that with the average height of the forage in inches, participants start getting an idea about how large an area a given herd would require daily.

Sounds complicated? Maybe so, but the result is that participants go home with the beginnings of a skill that they can develop with practice. Yes, the calculating required to start the training process can be complicated and cumbersome, but the skill developed can become quick and simple.

Another thing Jim talked about was his system of

"grazing the grass up". It's the same idea that I promote as "banking, or stockpiling pastures while grazing them". This is an incredibly important management system that helps to drought proof a pasture and is the basis for extending the grazing season.

This is done by grazing very lightly over each paddock while moving the herd quickly over the whole pasture while forages are growing fast. Then slowing the herd moves and increasing forage utilization as forage growth slows going into late summer and fall. This is a way of maximizing forage production with the short growing season we have. It's how my friend and GWFA Director, Iain Aitken stockpiles enough forages for grazing ten months of the year.

Jim also demonstrated very well, a saying I've come up with, "He who leaves the most behind, gains the most." I came up with this saying from seeing this idea as being common among the best graziers I know. Instead of grazing 1/2 of a stand of 6 inch grass to 3 inches, he's grazing 3/4 of a stand that's 16 inches tall, leaving 12 inches standing and using 4 inches of it.

*Thank you
Jim and Barb Bauer
for the evening
pasture walk!*

Foothills Forage & Grazing Association's Bus Tour to Neil Dennis' Intensive Grazing Operation

August 13 - 16, 2013
Carlyle Saskatchewan

\$500.00/person, double occupancy (+gst)
\$700.00/person, single occupancy (+gst)

Registration Deadline: July 12, 2013

Contact Laura Gibney: (403) 652-4900, laura@foothillsforage.com

Itinerary

- ♦ August 13: Travel from Calgary to Carlyle SK, overnight at Kenosee Inn in Moose Mountain Provincial Park
- ♦ August 14: Full Day at Sunnybrae Farm with Neil Dennis, overnight Kenosee Inn in Moose Mountain Provincial Park
- ♦ August 15: Travel to Lanigan SK, tour the Western Beef Development Centre, overnight in Saskatoon, SK
- ♦ August 16: Travel back to Calgary

Price Includes:

- ♦ Road travel departing and returning to Calgary on a coach bus with air conditioning, sound, TV, DVD and bathroom
- ♦ 3 nights accommodation
- ♦ Full Day Tour of Sunnybrae Farm, includes bag lunch and BBQ supper with Neil and Barb Dennis
- ♦ Tour of the Western Development Centre in Lanigan

Alberta Farmers Hope Crops Avoid Hail Damage this Year

Record Hail Last Year—Almost \$450 Million Paid on Hail Claims

As crops start to grow and another hail season begins, farmers across the province are hoping to be spared from the kind of record hail damage that battered crops in every part of Alberta last year.

"Last summer was the worst hail year we've ever seen. There were only 11 hail-free days all summer, from early June to mid-September," says Brian Tainsh, Manager of On-Farm Inspections with Agricultural Financial Services Corporation (AFSC), the Crown corporation that administers crop and hail insurance in Alberta on behalf of the provincial government.

Hail pounded crops in every region of the province from Foremost to Fort Vermilion, triggering more than 11,000 claims and record payouts of almost \$450 million through AFSC's Straight Hail Insurance program, and the Hail Endorsement rider that many farmers add to their crop insurance each spring.

"There wasn't one AFSC office across the province that didn't have hail claims reported," says Tainsh, noting the previous record hail year in Alberta was 2008 when hail claims totalled more than \$265 million.

Moisture Increases Hail Risk

What this year's hail season will bring is still anybody's guess, says Tainsh. He points out hailstorms in late May and early June have already triggered claims in the Vulcan and Lethbridge areas of southern Alberta—although crops at such early stages of growth have great potential to recover from hail damage.

Environment Canada Meteorologist Dan Kulak says it's too early to tell what the summer holds. "Alberta is a hail capital, so we know we'll get hail. The question is how much. A lot depends on what happens through the rest of June and how much moisture we have going into July. The wetter it is, the greater likelihood of hail," he says, noting high humidity last summer was a key factor that contributed to so many hailstorms.

Kulak points out there are three ingredients for hail - heat, surface moisture or humidity, and a trigger. "The sun is often the day-to-day trigger. It shines on the mountains, warming up the air, which then rises and often produces storms that move eastward from the foothills. If the warm air collides with cooler air moving in from the mountains, the storms can be intense. Alberta is designed for hail production and the mountains play a key role," he explains.

Early Hailstorm Protection

Tainsh says an increasing number of farmers are choosing to 'Auto Elect' Straight Hail coverage at the same time they purchase crop insurance in April. "It gives them a two per cent premium discount and protects their crops against hailstorms early in the season."

That early protection is important, he says. "If farmers wait and their crops are struck by hail before they're insured, any fields with more than 25 per cent damage become ineligible for Straight Hail Insurance for the rest of the season."

Straight Hail Insurance is available any time during the growing season at AFSC offices, and takes effect at noon the day after it's purchased. "Farmers also have the option of purchasing it online - giving them 24 hour access and a two per cent dis-

count," says Tainsh. "But first they need to contact AFSC for an activation code to enter the online site."

75 - Year Hail Mandate

It's been 75 years since Alberta passed special legislation giving AFSC its mandate to provide hail insurance in every corner of the province - even the highest risk areas, says Tainsh. "Many farmers couldn't get hail insurance back then because the risk was too high for private insurers to take on. That's why the Alberta Hail Insurance Board, which later became AFSC, was initially created - to ensure every Alberta farmer has access to hail insurance," he explains. "That's still an important part of our mandate today."

For more information about hail insurance, farmers can contact their nearest AFSC office or the Call Center at 1-877-899-AFSC (2372).

Submitted by AFSC

As the summer hail season begins, Brian Tainsh, with Agriculture Financial Services Corporation (AFSC), shows photos of the record hail that triggered close to \$450 million dollars in crop damage across Alberta last year through AFSC's Straight Hail Insurance program and the Hail Endorsement rider on crop insurance.

Director's Corner:

By: Cameron Jenkins

To protect my sheep from predators, I put them in a sheepfold each evening. In the last few weeks of torrential rain, my sheep fold all but washed away. (I realize this pales in comparison to what others went through during the flooding, but I like making mountains out of mole hills.) Because I did not manage things well beforehand, my sheepfold turned into a 6" deep mud pool that the sheep refused to enter. The result has been keeping my sheep in a poorly protected corral at night, with me sleeping in a camper close by.

Each of us has a vision for our farm, and livestock wallowing in muck was never part of mine. Sure, challenges arise. We are faced with tasks everyday that demand our attention. But when these tasks and challenges distract me from my vision, then I have a problem. These last few weeks have reminded me of where I'm heading. Managed grazing, healthy livestock on fresh grass: now there is a task worth the challenge.

Have You Noticed Any Little Black Bugs in Your Hay and Pasture Fields?

While walking through your hay or pasture fields you may have noticed a little black bug, commonly known as the Black Grass bug (*Labops hesperius*). This bug is native to western rangelands and is present in low numbers on native ranges, but has been known to increase in numbers when range-land is seeded to tame forages. Known to have bulging eyes on the sides of their heads, the Black Grass bug is sometimes referred to as the 'big eyed bug'. They are about 1/4 inch long, and have a whitish-buff colouring along the sides of their back and light coloured markings on their head.

How are the plants damaged?

The bugs feed on the upper part of the leaves and proceed down the leaf with their head facing downwards. By piercing the plant cell walls, the bugs are then able to suck out the liquid contents. The damaged plants look like they have been affected by frost.

Will the plants recover?

As with any plant disease or pest infestation, the healthier a plant is the more likely it is to recover. With adequate moisture, most damaged plants should be able to recover from the Black Grass bug.

What crops do they feed on and will they move into other fields?

Wheatgrasses tend to be preferred by the Black Grass bug, but if there are no grasses present they will feed on broadleaf plants. Researches in Utah conducted a study to see if these bugs preferred tame grasses over native forages. It was determined that tame grasses were consumed more often than native forages. The following list includes six tame grasses that were used in the test, ranked from most to the least susceptible to consumption: Intermediate wheatgrass, Kentucky Bluegrass, Slender wheatgrass, Orchard grass, Smooth Bromegrass, Mountain Bromegrass and native grass.

Black Grass bugs generally do not disperse from other areas, infestations are generally due to existing populations. The Black Grass bugs may move to the field edges of adjacent fields, but they do not move much farther than that. This is be-

cause majority of the females do not have fully developed wings.

What is the life cycle of these bugs?

The eggs are laid in the stems of the host plants and will start hatching around four to five weeks later. Black Grass bugs only have one generation per year and the nymphs feed and molt five times before they become adults. Temperature has an impact on the bugs as they mature more quickly in higher temperatures. After the bugs have reached maturity, the adults will lay eggs and then die.

How do you control Black Grass bugs?

In Canada, there are no insecticides registered for controlling this insect. However, in the United States both Malathion™ and Sevin™ have been used to control the bug. Other ways to control the Black Grass bug include grazing or haying fields late in the fall to remove the eggs.

Interesting Fact

Did you know that Grey Wooded soils are now called Grey Luvisol? The old name Grey Wooded continues to linger because it is such a good adjective for these soils; the soils are grey and they are developed under forests.

Please call **GWFA Manager, Albert Kuipers** at **(403) 844-2645** or your local County Agricultural Services staff if you would like to complete an Environmental Farm Plan. **Your EFP is required** to apply for funding to the Environmental Stewardships Plan Program of Growing Forward. Grazing & Winter Feeding, Integrated Crop Management and Manure Management are the 3 Stewardship programs that will be available in Growing Forward 2.

Alberta EFP
Environmental Farm Plan

Alfalfa Autotoxicity

When you are looking to breathe new life into an old alfalfa stand, alfalfa autotoxicity is one factor you will want to carefully consider before developing your rejuvenation plans.

What is autotoxicity?

Plants produce many different chemicals that they use to defend themselves from things like insects and diseases. Certain plant species give off chemicals that affect the growth and development of other plants. This is called allelopathy. Alfalfa has an allelopathic chemical that inhibits the growth of other alfalfa plants. It is said to be autotoxic, or toxic to itself.

What causes autotoxicity in alfalfa?

The autotoxic chemicals produced by alfalfa are water soluble and can leach into the soil from decomposing plant material and growing plants. The chemical causing autotoxicity in alfalfa has not been positively identified, but is thought to be ethylene and/or possibly medicarpin. The autotoxic chemical is found in higher concentrations in the leaves and flowers than the stems and roots of alfalfa plants.

What affects alfalfa autotoxicity?

As soon as a stand is killed, the autotoxic chemicals are released into the environment from the decomposing alfalfa plant material. Once they enter the soil, they will remain there until they break down or are moved by water. The length of time these toxic chemicals remain in the soil depends on soil type, temperature and rainfall.

On sandy soils, you will see more acute effects of the toxic chemicals, but they will last for less time than on heavier textured soils. This is because they will be quickly leached out by rain. On soils with more clay, the toxic chemicals are more strongly attached to soil particles, resulting in a lower level of damage over a longer period of time.

The age of the alfalfa stand affects autotoxicity. Stands that are two or more years old will contain more toxins than stands that are one year old or less. In addition, alfalfa plants have a higher level of toxins when flowering compared to alfalfa that is vegetative.

How does it affect alfalfa plants?

Both seedling emergence and growth are reduced by alfalfa autotoxicity. Plants that do emerge are often stunted and may show purpling, indicating a lack of nutrients. Root growth is most severely affected. Roots are swollen, discoloured, curled and lack root hairs. They end up branching more than normal and tend to be shallower. This negatively impacts the longevity of the stand, as it reduces the plants' abilities to take up water and nutrients.

Does it affect alfalfa yields?

Studies have shown yield reductions when alfalfa has been seeded after alfalfa, with no break in between. These yield reductions can be anywhere from 8 to 52% and persist for years. Stands affected by autotoxicity are also slower to regrow after harvest.

How long do I have to wait before reseeding a field to alfalfa?

If your alfalfa field is more than two years old, you should seed an alternative crop for at least one year after taking it out. This will give time for the autotoxic chemicals in the

old alfalfa stand to be released into the soil and to dissipate.

If you have a seeding failure or winterkill, you can successfully reseed that field the same summer or the spring following. The toxins are not present in the first year in new seedlings, meaning you don't have to worry about autotoxicity until the stand is two years old.

What about thickening on older stand?

It is not recommended to try to thicken an old stand of alfalfa with alfalfa. While you might get germination and seedling growth at the start, those plants will likely die out over the summer. This is because the size of the autotoxic zone around established alfalfa plants does not leave much space in a field where new seedlings could survive.

Studies have shown that the autotoxic zone is a 16 inch radius from an established alfalfa plant. New seedlings within 8 inches of established alfalfa plants often die, while those 8 to 16 inches away survive, but have stunted shoot growth and poor root development.

Could Pocket Gophers Improve Pastures?????

Last summer Iain Aitken, who is currently one of the GWFA board members, discovered that the areas on his pasture where pocket gophers disturbed the soil, had amazing regrowth. Once again, Iain has noticed this impact throughout his land this year. "I can't help but think something in this process holds the key to unlocking fertility and dramatically increasing forage yield if I better understood and could find a way to reproduce the mole effect," says Aitken. His curiosity led to the development of an on-going discussion between grazing experts, Grant Lastiwka, Ken Ziegler, Albert Kuipers, Phil Merrill and Brian Luce.

After doing a little research, Grant Lastiwka discovered an article by the Government of Manitoba which suggested that pocket gophers increase soil fertility by adding organic matter in the form of plant material and feces. Similar to an earthworm, the burrowing process increases soil aeration, and water infiltration, reduces compaction and increases the rate of soil formation by bringing subsoil to the surface. After reading this, you may begin to think twice about removing those pesky pocket gophers from your field as this all sounds pretty good, right? Well Phil Merrill's response was a little easier to relate to. "I believe a field heavily infested with pocket gophers loses production by merely loss of growing area of forage due to dirt mounds (up to 30% loss of growing forages in some fields)," states Merrill. "Pasture fields recover from mounding later on in the season with adequate moisture but hay land, particularly alfalfa, doesn't recover as well as it is cut quite early." He goes on to say that in subsequent years if the mound production decreased, then the old mounds would begin to produce better forage and there would be less bare dirt where forages weren't growing. Even though there may be some benefits to letting pocket gophers conduct their work, we all know that waiting for these benefits may cause more problems in the mean time.

Iain's response to these ideas was that he wasn't looking into increasing the pocket gopher population on his pastures, but rather an alternative way of producing a similar effect, such as the use of an AgroPlow. Brian Luce also raised another idea, perhaps poor biodiversity is the root cause of this whole issue. Whatever it may be, it certainly is an interesting observation made by Iain and perhaps something that should be looked into further.

Your Personal Invitation - Livestock Grazing, Climate Change and Alberta's Ecosystem

The Alberta Livestock and Meat Agency (ALMA) is presenting another world-class speaker to further our goal of creating an informed and engaged industry. In previous years, we've looked at strong companies and their business models (Greg Page, Cargill Chairman and CEO) and how to build Alberta product as an international luxury brand to China (Andrew Wu, LVMH Group President for Greater China). This year, we are focusing on climate change and the role of grazing livestock in land reclamation efforts. I am pleased to inform you that on Wednesday, July 17, Dr. Allan Savory of the Savory Institute will spend the morning with us, sharing his lifetime of research into how livestock grazing can have a beneficial impact upon our planet.

Dr. Savory was born in Rhodesia, South Africa. He pursued an early career as a research biologist and Game Ranger in the British Colonial Service of what was then Northern Rhodesia (today Zambia), and later as a farmer, game rancher, politician and international consultant, based in Southern Rhodesia (today Zimbabwe). In the 1960s, while working on the interrelated problems of increasing poverty and disappearing wildlife, he made a significant breakthrough in understanding what was causing the degradation and desertification of the world's grassland ecosystems. He went on to work, as a resource management consultant, with numerous land managers (eventually on four continents), to develop sustainable solutions.

His early results in reversing land degradation in a manner that made, rather than cost, money were impressive. But, as he often states, his failures were equally impressive. Finally, in the mid 1980's the last of some key missing pieces fell into place. Since then, thousands of land, livestock and wildlife managers have demonstrated consistent results following the methodology Savory called "holistic management."

In 2003, Dr. Savory was awarded the Banksia International Award for the person or organization doing the most for the environment on a global scale. His current work in Africa is receiving much praise and recognition and the Africa Centre for Holistic Management was announced the winner of the 2010 Buckminster Fuller Award for the organization working to solve the world's most pressing problems.

Join us at the BMO Centre Boyce Theatre in Stampede Park, Calgary. The event starts with coffee and a light snack at 9 a.m., with Dr. Savory presenting at 10 a.m. A light luncheon will follow the presentation.

I do hope you accept this invitation and attend the event.

With kind Regards,

Gordon Cove
President and CEO, ALMA

Date: July 17, 2013

Location: Boyce Theatre, BMO
Centre

Registration and Reception at 9
a.m. Presentation to begin at 10
a.m.

Lunch served in the Palimino
Room at noon. Parking available
at Lot #10, cost \$15.

Please RSVP by July 10

Practical Information for Alberta's Agriculture Industry

October 2004

Agdex 420/52-4

Beef Ration Rules of Thumb

This factsheet can both guide producers through a feed test and help them understand the results.

With a feed test in front of you, look at the following rules and compare them to the feed test. Remember, these are rules of thumb, which means they hold true most of the time, but variations in management and cow type will affect the end result.

These rules of thumb should not be considered a replacement for balancing rations with proven software, but rather an aid to understand the feed and where it fits in the management.

Rules of Thumb

Dry matter

Always refer to the "dry matter" numbers. These numbers have the moisture factored out and allow the comparison of all feeds, from silage to grains.

Crude protein

Protein is a building block. The Beef Cow Rule of Thumb with protein 7.9-11, which means an average mat requires a ration with crude protein < pregnancy, 9 per cent in late pregnancy.

Energy

Energy gives the ability to use the building blocks for growth and other productive purposes. Learn one of the six measures for energy and stick with it. Using Total Digestible Nutrients (TDN) per cent, the Rule of Thumb is 55-60-65. This rule says that for a mature beef cow to maintain her body condition score (BCS) through the winter, the ration must have a TDN energy reading of 55 per cent in mid pregnancy, 60 per cent in late pregnancy and 65 per cent after calving.

August 2004

Agdex 130/52-1

Nutrient Management on Intensively Managed Pastures

September 2004

Agdex 420/56-3

Agronomic Management of Swath Grazed Pastures

Fod, feeding, cow management and manure disposal can account for up to two-thirds of the total cost of production in a cow-calf operation. Systems that can extend the grazing season and reduce these costs are of great interest to cow-calf producers. One of these is swath grazing.

Many factors come into play to determine forage quality, quantity and unit cost of production in a swath grazing system. Some of these factors, such as weather, are outside the producer's control. Other factors are controllable.

Pools and pathways

Several pools of nutrients include organic matter, growing plants (short), plant litter, living animals (livestock, herbivores, above and below ground invertebrates (beetles, ants) and soil macrobes, and the atmosphere.

Nutrient cycles develop as nutrient pathways from one pool to another. The length and complexity of nutrient cycles are different for various nutrients, but nutrient balances control the cycles. Balances are made up of inputs, outputs and losses of nutrients in the pasture system.

$\text{inputs} = \text{outputs} + \text{losses}$

Inputs are those removed or added to the system.

Agronomic Management of Stockpiled Pastures

Stockpiling pasture is a form of deferred grazing. The producer stockpiles the forage grown during the spring and summer for use when the pasture is in short supply or when cows need fall or winter feed. This practice can mean savings for the producer:

- harvesting, hauling and feeding costs associated with mated

! to be removed from feeding

: range is

: species. Depth

: limits winter

: in the

: st. regions,

: soon may be

: by using

: fall and early

: stems

: for a full growing season, for a

: regrow rapidly following early harvests to provide at

: least 2,000 kilograms (kg) of forage per hectare

: (1,785 lb/ha) for good fall grazing

: maintain high quality following fall frosts

: if grazing is to occur after snowfall, forage mass needs to

: be higher as grazing efficiency is reduced and grazing

: losses increase. Using an erect species makes it easier for

: cows to get at the feed under the snow.

: In a single-pass system, a species that maintains its quality

: as it matures is a good choice.
